Abstract

ADS require a high-intensity proton accelerator of which energy and beam power are about 1 GeV and 20-30 MW, respectively. JAERI, KEK, MHI and MELCO have conducted a programme for the development of a superconducting proton linac for the ADS since 2002. This programme, which is based on the achievement of the J-PARC design work, consists of two parts, development of a 972-MHz cryomodule and system design of a superconducting proton linac in the energy range between 0.1 and 1.5 GeV. In the development work of the 972-MHz cryomodule, a prototype cryomodule which includes two nine-cell cavities of $b = 0.725$, will be developed and the goal is stable operation in the horizontal tests at the surface peak field at 30 MV/m. In the system design work, a preliminary beam dynamics design has been determined with the configuration of a cryomodule with two 972-MHz, nine-cell elliptical cavities, and a room-temperature focusing magnet. This paper provides the present status of the cryomodule development and the system design.

Introduction

JAERI proposes an ADS which consists of superconducting proton linac, spallation target of lead-bismuth eutectic and a subcritical core. In this proposal, the energy and beam power of the superconducting proton linac are 1.5 GeV and 20-30 MW, respectively. JAERI has conducted an R&D programme for the ADS since 2002 in collaboration with national laboratories, universities and companies. This programme includes R&D on a superconducting proton linac, lead-bismuth technology and subcritical core design and technology.

The R&D on the superconducting proton linac, which is based on the achievement of the J-PARC design work, consists of two parts, development of a 972-MHz cryomodule [1] and the system design of a superconducting proton linac in the energy range between 0.1 and 1.5 GeV.

In the development work for the 972-MHz cryomodule, which is conducted by JAERI, KEK and MHI, a prototype cryomodule is currently being assembled. The cryomodule includes two 972-MHz nine-cell cavities of $b = 0.725$. The goal of this work is stable operation in the horizontal tests at the surface peak field at 30 MV/m, which corresponds to an accelerating gradient of about 10 MV/m. The cavity development, which includes the vertical tests, is mainly being performed at KEK. The horizontal tests will be performed at JAERI, where a 972-MHz klystron, also utilised for the high-power tests of the power couplers, is in operation.

In the system design work, which is conducted by JAERI, KEK and MELCO, a preliminary beam dynamics design has been established with a configuration of a cryomodule with two 972-MHz, nine-cell elliptical cavities, and a room-temperature focusing magnet. The total number of cryomodules and their length are outlined in this work.

Cryomodule development

Cryomodule design

Figure 1 shows an overview of the cryomodule. Two 972-MHz nine-cell elliptical cavities are installed in the cryomodule, for which the operating temperature is designed to be 2 K. Each cavity is surrounded by a jacket-type liquid helium (LHe) vessel made of titanium. A box-shaped LHe reservoir tank, which is located above the cavities, connects both LHe jackets.

Figure 1. Overview of the prototype cryomodule

Coaxial-type power couplers, of which the inner and outer diameters are 34.7 mm and 80 mm, respectively, are located at the centre of the cryomodule. KEK-TRISTAN-type disk windows are placed at the room temperature region. Inner conductors of the power couplers and the windows are cooled by water. Cooling of the outer conductors is achieved by thermal intercepts at 5 K and 80 K. A high-power test of the power couplers was carried out successfully with a maximum RF power of 1 MW in pulsed mode operation; the pulse width and repetition rate are 0.6 ms and 25 Hz, respectively. Details of the power coupler design and the test results are presented in Ref. [2]. A higher-order mode (HOM) coupler is attached at both ends of each cavity. The HOM couplers located at the power coupler side are made of niobium and are designed to be cooled by LHe. The HOM couplers located at the outer side are made of copper without any cooling because of the reduced heating. Details of the design for the HOM coupler are presented in Ref. [1].

The tuning system consists of pulse motors and a piezo actuator is located outside the cryomodule. Each LHe jacket includes bellows and tuning force is applied from the tuning system with coaxial rods.

The heat shield at 80 K is installed in the cryomodule and is cooled by liquid nitrogen (LN₂). Thermal intercepts at both 80 K and 5 K, which are cooled by LN₂ and LHe, respectively, are also installed at power couplers, beam pipes and tuning rods. The cavity support is cooled by LN₂ at 80 K and the thermal insulation between the support and the cavity is achieved by GFRP. In order to achieve operation of the cavity at 2 K, a JT valve is installed in the cryomodule. Therefore, the cryomodule has three independent cryogenic flows, LN₂ at 80 K, LHe at 5 K and 2 K. The static heat load for each flow is estimated: 64 W, 16 W and 5 W for 80 K, 5 K and 2 K, respectively. A magnetic shield made of permalloy is installed just on the inner side of the vacuum vessel of the cryomodule.

Superconducting cavity

Figure 2 shows the shape of the 972-MHz, nine-cell cavity of $b = 0.725$, which includes the surrounding LHe jacket. The cell length and the total length including beam pipes are 112 mm and 1 397 mm, respectively. The equator and iris diameters are 277 mm and 90 mm, respectively, while the beam pipe diameter at the power coupler side is expanded to 126 mm in order to obtain sufficient external Q of the power coupler of $5 \cdot 10^5$. The RF parameters of this nine-cell cavity are summarised in Table 1 [3]. The wall thickness of this cavity is 3.8 mm, which is thicker than other superconducting elliptical cavities in order to provide the stiffness and to reduce the Lorentz force detuning. As the stiffness of the LHe jacket is also important to reduce the Lorentz force detuning, the shape of the end plates of the jacket was optimised so as to obtain sufficient stiffness. The stationary Lorentz force detuning was calculated to be 130 Hz at the surface peak field of 30 MV/m (i.e. accelerating field of about 10 MV/m).

Figure 2. 972-MHz, nine-cell elliptical cavity of $b = 0.725$

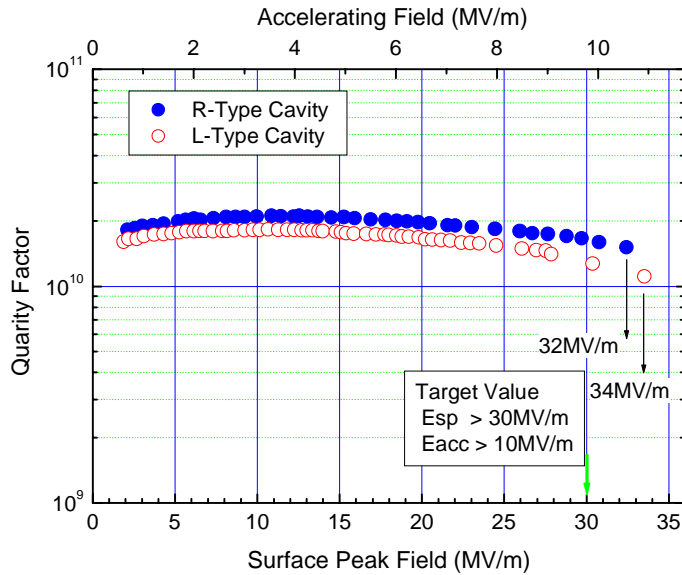

Table 1. RF parameters of the cavity

Esp/Eacc	3.07
Hsp/Eacc	55.4 Oe/(MV/m)
R/Q	478 Ω
Geometrical factor	208 Ω
Cell-to-cell coupling	2.80%

For the fabrication of the cavity, a new approach was applied in deep drawing; the shape of the die was optimised so as to minimise the forming error using a structural analysis and an error of less than 0.3 mm was obtained [4]. Pre-tuning was performed after fabrication of the cavity and field flatness above 98% was obtained for both cavities [5]. Vertical tests of the cavities at 2 K were carried out after the surface treatments of barrel polishing and electropolishing. Figure 3 shows the final results of the vertical tests. Surface peak fields of 32 MV/m and 34 MV/m were obtained for two cavities (type-R and type-L cavities), which satisfied our target value of 30 MV/m.

Figure 3. Final results of the vertical tests of the cavities

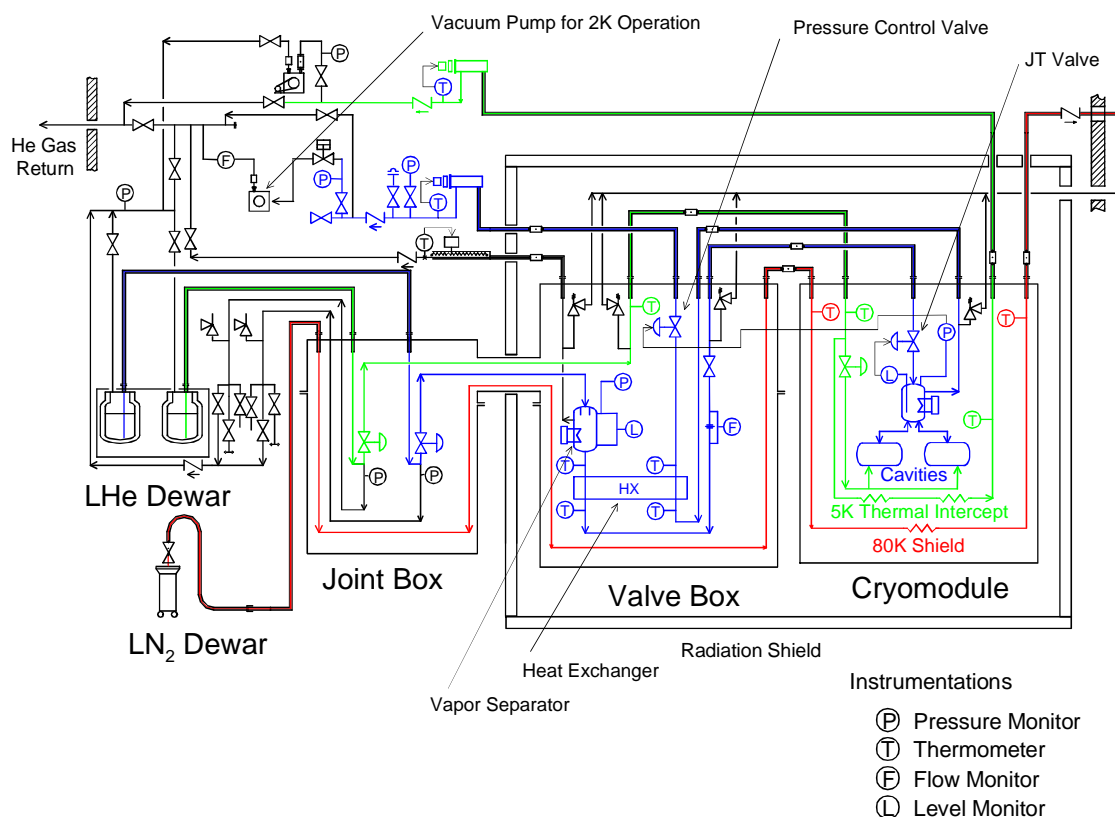

Cryogenic system for horizontal test

As described in the previous section, the cryomodule has three independent cooling lines of LN₂ at 80 K, LHe at 5 K and 2 K. Figure 4 shows a flow diagram of the cryogenic system for the horizontal test. The cryogenic system consists of the cryomodule, the valve box, the joint box, Dewars and other auxiliary components. Refrigerant for each line is fed from portable Dewar individually. The valve box is installed for connection and feed control of the refrigerants to the cryomodule. In the superconducting linac of the ADS plant, a similar valve box will be installed while the refrigerant will be fed directly from a refrigerator. The joint box is installed for the connection between the valve box and the Dewars, which is designed so as to exchange the Dewar during the experiment.

As for the line of LHe at 2 K, the LHe vessel is evacuated to about 4 kPa by a vacuum pump at the room temperature region. A vapour separator and a heat exchanger are equipped in the valve box in order to increase the production efficiency of LHe at 2 K in the cryomodule. The JT valve in the

Figure 4. Flow diagram of the cryogenic system for the horizontal test

cryomodule produces the superfluid LHe and controls the LHe level in the LHe vessel. A valve placed on the He gas return line in the valve box performs pressure control of the LHe vessel, thus also temperature control of the LHe.

As for the line of LHe at 5 K, a valve in the joint box performs the flow control. In the cryomodule, this line is connected to the LHe vessel, which is used for the cooling down from room temperature to 5 K.

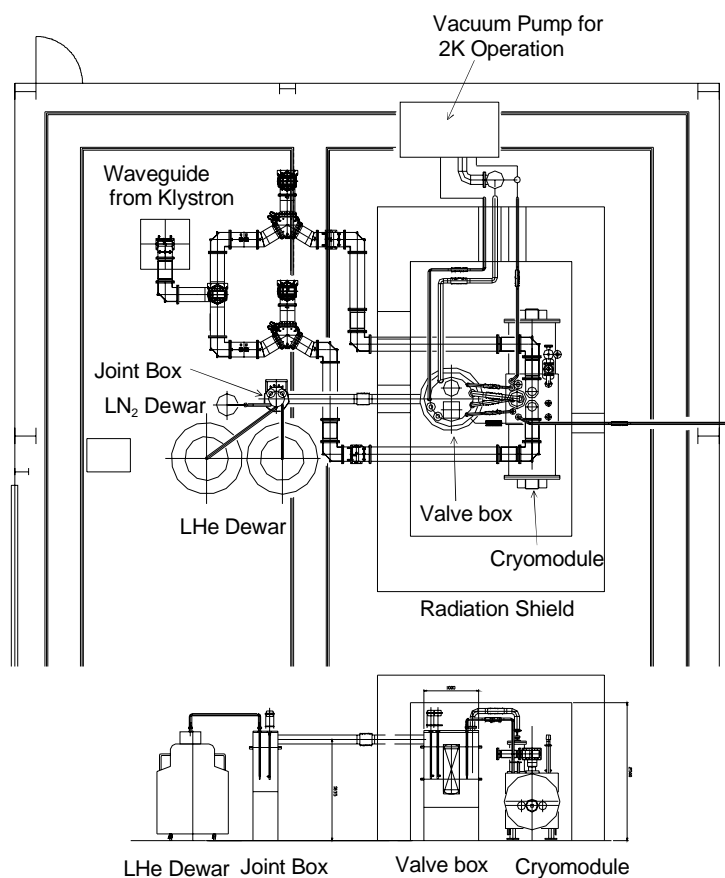

As for the line of LN₂, no control valve is placed in the cryomodule, the valve box and the joint box. The valve at the LN₂ Dewar performs the flow control manually.

Experimental arrangement and schedule of the horizontal test

The experimental arrangement of the horizontal test of the cryomodule is displayed in Figure 5. The cryomodule and the valve box are located in a radiation shield. The joint box, Dewars and the vacuum pump are located outside of the shield. An RF power source, klystron, is located at a lower level. A waveguide system is connected from the klystron and the RF power is divided for two cavities.

Final assemblage will be soon be complete at the JAERI Tokai site. The horizontal test is planned for 2004. In the test, the RF high power test will be performed for the final goal of the surface peak field of 30 MV/m. Additional testing planned includes cryogenic tests and low-level RF tests, including heat leak and temperature distribution measurement, a control test at 2 K operation, measurements of quality factors for the accelerating mode as well as HOMs, tuning tests and so on.

Figure 5. Experimental arrangement of the horizontal test

System design of superconducting linac for ADS

In the system design work, a preliminary beam dynamics design of the superconducting proton linac has been established in the energy range between 100 MeV to 1.5 GeV.

Basic design parameters

Table 2 shows the basic parameters for the beam dynamics design. In this energy range, the β value changes from 0.428 to 0.923. Parameters of accelerating frequency, number of cells in a cavity, number of cavities in a cryomodule and maximum surface peak field are set to be the same as the parameters of the prototype cryomodule. Phase slip in a cavity, which comes from a mismatch between beam β and cavity cell length, is set to be within -30° in order to obtain smooth bunching, as the synchronous phase angle is set to be -30° . According to this condition, the number of cavity groups is deduced to be 10 in the energy range 100 MeV to 1.5 GeV, which is larger than other superconducting linac designs because of the larger number of cells in a cavity of nine. The focusing magnet is considered to be a quadrupole doublet in a room temperature region between the adjacent cryomodules. The schematic view of the lattice structure is shown in Figure 6. The zero current transverse phase advance is set to be 70° , which is constant in a superconducting linac region. The longitudinal phase advance is obtained from the accelerating field of the cavity, while the maximum longitudinal phase advance is limited to 65° to avoid structural resonance in the beam dynamics.

Table 2. Basic parameters for the beam dynamics design

Energy range	100~1 500 MeV	Beam current	20~30 mA
b range	0.428~0.923	Synchronous phase	-30
Accelerating frequency	972 MHz	Phase slip in a cavity	Within -30
No. of cells in a cavity	9	No. of cavity groups	10
No. of cavities in a cryomodule	2	Focusing magnet	Room temperature
Max. surface peak field	<30 MV/m	Transverse phase advance	70 (I = 0A)

Figure 6. Schematic view of the lattice structure

Preliminary superconducting cavity design

Preliminary designs of 10 kinds of superconducting cavities have been established in order to obtain the ratios of the surface peak field to the accelerating field and the transit time factors. Table 3 summarises the RF parameters of the cavities.

Table 3. RF parameters of the cavities

b	Esp/Eacc	Transit time factor	R/Q (W)
0.444	7.40	0.634	87.38
0.480	6.27	0.648	121.23
0.518	5.34	0.662	162.67
0.560	4.70	0.673	215.48
0.604	4.07	0.685	278.75
0.653	3.60	0.695	356.10
0.705	3.16	0.702	443.28
0.761	2.84	0.708	543.37
0.822	2.56	0.715	661.44
0.888	2.30	0.721	749.59

Lattice design

As shown in Figure 6, drift spaces between two cavities in the cryomodule, and between the cavity end and qadrupole magnet are set to be 500 mm and 980 mm, respectively. The effective length of the quadrupole magnet and drift space between the doublet are set to be 240 mm and 410 mm, respectively. These parameters are the same as for the superconducting linac design of the J-PARC project.

Table 4 summarises the structure of the superconducting linac. In this design, 106 cryomodules, i.e. 212 cavities, are necessary in the energy range from 100 to 1 500 MeV and total length is 560 m. As shown in Table 4, the lower-energy part, especially the 100-180 MeV region, is quite inefficient; 21 cryomodules and 100 m are necessary. The main reason for this inefficiency is a higher E_{sp}/E_{acc} ratio. Optimisation of the lattice design as well as the cavity design is necessary for the final design of the superconducting linac.

Table 4. Basic structure of the superconducting linac

	Cavity b	Beam b	Beam energy (MeV)	No. of cryomodules	Length (m)
1	0.444	0.428~0.462	103.1~122.7	7	32.1
2	0.480	0.462~0.499	122.7~147.3	7	32.8

10	0.888	0.855~0.923	876.5~1 510	29	168.6
Total				106	564.8

Beam simulation

Beam simulation of the superconducting linac was performed using the TRACE-3D and modified PARMILA codes. In the simulation, the initial beam emittances are referred from the J-PARC beam design data. As an example of the results, Figure 7 shows the 90% emittance in both transverse and longitudinal directions. As shown in the figure, emittance growth is not observed in the beam simulation results.

Figure 7. 90% emittance obtained in the beam simulation

Conclusion

The development of a superconducting proton linac, cryomodule the system design are ongoing. As concerns the cryomodule, fabrication has been completed and final assemblage will soon be finished as well. The horizontal test will be performed in 2004 toward the goal of a maximum surface peak field above 30 MV/m. Regarding the system design, a preliminary beam dynamics design has been determined. The present result, however, provides more cryomodules and a longer total length than expected. Additional optimisation is thus necessary.
